Salmonella Cerro

**Background:** *Salmonella enterica* subsp. *enterica* serovar Cerro (antigenic formula 6,14,18:z<sub>4</sub>z<sub>23</sub>:1,5) is a serovar of the O:18 (K) serogroup. This serovar emerged in cattle in the United States. According to the CDC report of 2011, this serovar ranked third among clinical-nonhuman sources. Hardly reported in human salmonellosis cases, but highly reported among dairy cattle; *S. Cerro* appears to be adapted to cattle. Subtyping by pulsed field gel electrophoresis (PFGE) had identified a single predominant PFGE type on dairy farms in New York and Pennsylvania. Genomic characteristics associated with the adaptation of *S. Cerro* to cattle are currently under study at the Cornell Food Safety Laboratory and Dr. Cummings' lab at Texas A&M University.

**Animal reservoir:** *Salmonella* Cerro has as reservoir dairy cattle. Some endemic regions include New York and Pennsylvania.

**Geographical distribution:** *S. Cerro* has been reported mainly in the U.S. (from bovine samples). In addition, in southern Italy, this serovar was described as endemic in the year 2000.

**Outbreaks:** Two outbreaks of human salmonellosis due to serovar Cerro has been reported. The most recent one occurred in 2 prisons in 2012 and was attributed to multiple serovars, including *S. Cerro*. In addition, one subclinical outbreak in dairy cattle was reported, in this outbreak contamination at the farm persisted for almost 2 years.

*The total case count was n=597, and a total of 60 and 106 *Salmonella* isolates were cultured from 56 (Prison A) and 99 patients (Prison B), respectively. *Salmonella* Cerro was isolated from 6 patients that were co-infected with other serovars, and 8 isolates were obtained from the egg samples.
